

Green sea turtles
consume approx.
2 kg of seagrass
leaves per day

Help seagrass

There are many ways you can help: don't litter, be aware when applying fertilizers and pesticides, as excess amounts can wash down gutters and drain into the ocean; when boating, slow down and avoid shallow areas; support marine conservation initiatives; learn about these special marine habitats and volunteer to monitor their health by joining Seagrass-Watch.

Seagrass-Watch: Global Seagrass Observing Network monitoring efforts are vital to assist with tracking global patterns in seagrass health, and assess the human impacts which have the potential to destroy or degrade these coastal ecosystems and decrease their yield of natural resources.

To protect valuable seagrass meadows everyone must work together.

Seagrasses of Dunk Island

About Us

Seagrass-Watch: Global Seagrass Observing Network is one of the largest long-term seagrass observing programs globally, and is highly recognised for its scientific rigour.

Participants all share a passion in marine conservation.

Participants involved in the Global Seagrass Observing Network develop a deep sense of custodianship and understanding of their local marine environments that reaches throughout the wider community.

About seagrass

Seagrasses are the only marine flowering plant. There are approximately 60 seagrass species (possibly 72) globally that belong to four major groups. Seagrasses are not seaweeds. Seaweed is the common name for algae.

Seagrass live in sheltered coastal waters, undergo pollination while submerged and complete their entire life cycle underwater. They grow much like land grasses, with extensive below ground rhizomes or runners. Plants form small patches that develop into large continuous meadows. These meadows may consist of one or many species, sometimes up to 12 species present within one location.

Importance

Seagrass is one of the most productive natural ecosystems globally. Seagrasses are as important as forests in storing carbon (on an areal basis) and can store carbon 35 times faster than rainforests.

Seagrass occupy less than 0.2% of the world's oceans, but are responsible for more than 10% of all carbon in ocean sediments annually.

Seagrasses improve water quality by acting as nutrient sinks, buffering/filtering nutrient/chemical inputs to the marine environment. They also stabilise marine sediment and help avert erosion.

Seagrasses provide food and shelter for many organisms including Sea turtles and dugongs.

Dunk's seagrass

Nine seagrass species can be found in waters surrounding Dunk Island, with most present on the western side.

Scattered over sandy areas exposed at low tide you will find *Halodule uninervis* and *Halophila ovalis*, both food for dugong. On the sand bank to Kumboola Island, is *Cymodocea serrulata* and *Cymodocea rotundata*, often eaten by green turtles that visit the reef flat during high tides.

Mixed in amongst the coral on the reef flat you will find *Thalassia hemprichii*. Closer to the islets and reef edge, you will find patches of *Syringodium isoetifolium*.

In the deeper waters (>3m) off the sand spit, is *Halophila decipiens*, a clover like species which has "hairy" leaves. Toward the mainland, you may find the fern like *Halophila spinulosa* or the rare *Halophila tricostata*, which has oval shaped leaves arranged in clusters on a vertical stem.
